Charging up India's Electric Vehicles

By Pradyumna Bhagwat, Samson Umarey Hadach, Anitha East Karim Bhagwat
Florence School of Regulation

Issue 2021/1
October 2021

POLICY BRIEF

India's ambitious electric mobility targets are highly dependent on the availability of robust charging infrastructure and incentives of the power system to integrate the additional flexible EV load.

India's participation in state and national level on-procurement bidding schemes for developing EV charging infrastructure (EV service providers on supply side and EV users' (demand side) further enhancement for supply side can come from the role of distribution companies (DISCOMs), tariff design incentives, permitting processes and data privacy, and on the demand side from personal mobility, residential facilities, charging station non-regulation and consumer considerations.

EV charging business in India is in its early stage, and it has a large scope for business model innovation. As EV penetration increases and market grows, innovations can be expected in the areas of service provision, permitting and pricing.

EV load can increase peak demand and distribution grid congestion. Solutions are emerging to avoid these stresses in generation and network capacity such as time-varying tariff and flexibility resources related to the DISCOMs and with these firms.

EVs is still in its early stage but would become vibrant in the medium term. The success in providing the stability of EVs requires and necessitates multiple entry barriers for EV service providers can be improved through aggregation, allowing smaller operators to reduce and contract periods, common standards and interoperability.

The search for the most appropriate solutions would benefit from regulatory conditions both at the national and state level.

Dynamic Retail Electricity Tariffs: Choices and Barriers

By Pradyumna Bhagwat and Samson Hadach
Florence School of Regulation

Issue 2021/1
April 2021

POLICY BRIEF

System innovation can assist on the implementation of dynamic retail electricity tariffs are reviewed to identify the design and implementation choices that have to be made when introducing such tariffs.

Two primary design choices are identified: 1) the time block length, which means the number of dynamic tariff levels, and 2) the price periodicity, which is the time interval between increments of the tariff. Time of use tariffs are widely used and they can be the first step in applying dynamic tariffs before moving to more advanced approaches such as real-time pricing.

Two types of implementation choices are identified: 1) those made by the regulator regarding regulatory interventions to protect vulnerable customers; and 2) those made by consumers regarding whether to opt for a dynamic tariff and the selection of a suitable dynamic tariff option.

The implementation of dynamic retail tariffs depends on the availability of physical and administrative and communication technology (ICT) infrastructures, the maturity of the power market design and consumer behaviour.

Before implementing dynamic tariffs, it is essential to conduct a careful cost-benefit analysis of the effects on consumers, suppliers and the overall implementation system. Moreover, enabling innovation, business models and technologies will help to derive the maximum benefits from the application of dynamic tariffs.

The policy brief is based on research conducted by the Florence School of Regulation as part of a research study for the Africa Energy Grid Forum funded by the Health Research Council Foundation.

Expert survey on Energy Storage Systems: regulation and policy from an Indian power sector perspective

FSR Working Paper 2021

21st Century Novelty 1: Innovation(s)

Incentive Regulation assumed that companies innovate on their own:
Getting Opex lowered, Performances increased, to handle risky contracts taken from the Menus, etc.

10 years ago, it became clear that innovation had to accelerate (digitalization as smart grids, smart metering) and had to enter into all parts of incentive regulation. British regulator redefined regulation:

>> RIIO >> Regulation as “*Revenues = Incentives + Innovation + Outputs*”

- What's new for regulation?
- Innovation is to face the unknown, to take risks, to do trials & errors. Regulator has to be lenient: it can return to ‘**cost of service**’ for testing & running experiences; to **grants** for undertaking innovation; to **increased ROR** for Capex uncertainty
- Big novelty = “Sandboxing”: where companies learn; the regulator too. With more knowledge, innovation can marry better with the ‘classic’ incentive regulation

21st Century Novelty 1: Innovation(s)

- Incentive Tools can adapt to innovation

*If innovation lowers costs, it can enter **Price Cap**; Capex too can enter Price Cap: **TOTEX** can substitute to **(Opex Price Cap + RoR for Capex) > future decrease of TOTEX to be shared between company & society**

**If innovation increases performances that can be measured;

Performance Based Regulation

Renewables capacity hosted by the grid: performance better than predefined targets = extra reward; worse = punishment

***If innovation requires strong skills: **Menu of Contracts** Only people with strong skills will take more rewarding / more risky contract

UK offshore sea grid: generators can define &

build them if they want; then reselling these sea grid assets to sea grid franchisee by auctioning, before starting normal offshore operation.

More innovation to come offshore

To come: Danish offshore hub; 10-20 GW energy islands. What regime?

Novelty 2: “Coupling Regulation(s)” to get Sector Integration

Just seen that “Incentive Regulation + Innovation” can create structural changes like “new modules of regulation” separated from the general regime of regulation (UK: Offshore grids; Denmark: Offshore hubs)

Many other cases of “New regulatory modules / Local regulatory regimes” like:

- ❖ Rural microgrids, minigrids to give access to electricity
- ❖ Auctions for utility-scale solar parks, or wind farms, with FiT
- ❖ Local storage, for grids to balance RES intermittency
- ❖ Planning of charging stations, for EVs & E.bikes
- ❖ Creation of city gas infrastructures, to decrease local air pollution
- ❖ Green Hydrogen industrial valleys

>> All these new modules de-integrate the regulatory frame; create new particular regulatory regimes for particular classes of infrastructure assets or technological systems.

Novelty 2: “Coupling Regulation(s)” to get Sector Integration

However these new modules can enter the ‘general regulatory frame’ in a 4 step process

Step 1- Rolling out of the new infrastructure, or infant technical system, with its particular set of rules

Step 2- At a maturity point; decision if (Unbundling) & (Nomination of a regulated operator) is needed

Step 3- Definition of a maturity regime: (Definition of a Code of operation of this infrastructure or system) < < **Alignment** >> (Rules of Market Design; maybe with market operator)

Step 4- This modular maturity regime evolves with successive realignments of the pair { infrastructure operation code) & (rules of market design} to operate smoothly this pair, in coordination of general regime of regulation

“Coupling of all Regulatory Regimes” might end up in a general “Sector Integration”: all different energy sectors & vectors get aligned

Novelty 3 “Dynamic Regulation” to respond to “Prosumer Revolution Spiral”

“Innovation(s)” created “new modules of regulation”...

NOW: one single structural change can transform the entire regulation landscape...

Classics of regulation (*Monopoly + Costs of service*) or (*Markets + Incentive regulation*) were both assuming that consumers need access to monopoly grid to get served: a state of dependence

“Prosumer” breaks that by investing: into self-generation, self-consumption, self-storage, self-management of individual load

Any decision by regulator, or any regulated operator, is followed by prosumers striking back: in their behaviour, investments, operation of assets, new decisions to become prosumer, etc.

Novelty 3 “Dynamic Regulation” to respond to “Prosumer Revolution Spiral”

Regulator & Regulated Operator cannot assume that their own alignments - just seen in Update2- will work as they would like
[[(Code of operation of the infrastructure or technical system) < < Alignment >> (Rules of Market Design; maybe with market operator)]]

“Prosumer Revolution Spiral”: the whole regulatory regime has to evolve - with successive realignments of its various pairs {infrastructure operation code} & {rules of market design} to respond to actual decisions taken by active prosumers

>> “Dynamic Regulation” = continuously coupling the various “Regulatory Regimes” with new reactions / new decisions taken by Prosumers

Novelty 4 “Dynamic Regulation” becoming 3D pushed by Multilevel digital interactions

The idea of “dynamic regulation” acknowledges that a new player (the prosumer) has enough incentives & liberty of decision-making to always react to regulator & regulated operators’ decisions.

“3D Dynamic Regulation” is the new system we are entering in.

The electricity system is incredibly changing, in all its dimensions: it’s becoming 3D. ..

From the top to the bottom within its frontiers, as well as behind or beyond its frontiers (think EVs, interactive buildings, Green H2...)

“3D Dynamic Regulation” = continuously coupling the classical “Regulatory Regimes” with novelties popping anywhere...

Novelty 4 “Dynamic Regulation” becoming 3D pushed by Multilevel digital interactions

***Distributed energy resources, *self-generation & self-consumption, *self-storage, *demand response, *charging electric vehicles, etc. are managed with decisions taken “beyond electricity regulation” and “behind the meter”...**

The classical electricity system was made of “Transmission & Distribution” encapsulating Generation

A new level of electricity system appears today at its “bottom”: the individual decisions taken “Behind-the-Meter”

“3D Dynamic Regulation” = the electricity system is become multilevel... not anymore controlled by a single “system operator” & its “central dispatch”...

Novelty 4 “Dynamic Regulation” becoming 3D pushed by Multilevel digital interactions

Electricity system is not only become “Multilevel”; it is also become “digitally interactive” in all its dimensions

Digitalisation continuously enables new players, permits new products, favours new types of trade arrangements: **towards generalized digitalization, with 5G & “Internet of Things”**

❖ **New Players**

Aggregators, prosumers, energy communities, asset fleet managers, platforms

❖ **New Products**

Realtime green energy, blockchained generator, sharing local storage, “smart” charging EV, flexibility as “V2Grid”, automated load management

❖ **New Trade arrangements**

C2B, C2C (Peer2Peer – Blockchain), two-sided Markets (platforms)

“3D Dynamic Regulation” in Multilevel digital interactions

Ones still have to align (**Operation of Infrastructures & Technical Systems**) with (**Rules of Market Design**) but...

Handbook on Electricity Markets

Edited by Jean-Michel Glachant, Paul L. Joskow, Michael G. Pollitt

17. New business models in the electricity sector
*Jean-Michel Glachant**

1. INTRODUCTION

A new wave of deep changes is beginning to shake the electricity sector as we enter the third decade of the twenty-first century. Having an earlier wave in the last decade of the twentieth century, we already know that it can happen. In the 1990s, it was the combined cycle gas turbine (CCGT) and the open wholesale market – a new type of asset to generate electricity and a new framework to price and trade electricity between ‘wholesale size’ units. Today, key trends are represented, on the one hand by windmills and solar PV panels, and on the other hand by a deepening digitalization of price and trade electricity between ‘retail size’ units. Of course, these new trends are only beginning, and they will not present the same characteristics or occur at the same pace in different electricity sectors around the world. It will depend on what the former wave of change in electricity already did or did not do: whether wholesale and retail markets are open to entry and competition, whether vertically integrated companies and/or national governments control investments, technology choices, siting of new assets, tariffs and support schemes; and whether market and grid operations are ruled by a government administration, the industry itself or an independent body and so on.

Various chapters in this handbook explore concrete cases around the world, both in developed and developing countries. What the present chapter will concentrate on are new changes emerging in western countries that have already been implementing the open wholesale market model for 20 or 30 years. These new changes appear both on a large scale – such as the ‘pricing of electricity’ – and on a smaller scale – such as the deepening digitalization of ‘retail-size’ units. While still being relatively new, post-2010, these changes are already significant enough to be of great interest, not only for the future of those electricity sectors that have been liberalized, but also for those that are not – or not yet – market based!

In a market-based industry, business models are key – as propellers for investments, for technology choices, for the definition of the characteristics of the products and for the siting and operation of the asset base. The business model literature identifies up to nine possible components of sophisticated business strategies (Osterwald-Lerner and Clark 2010). A simpler and still robust version can be built with only two pairs of components of business model differentiation: first can be the type of assets that are engaged and the revenue streams they can secure; second can be the definition of particular characteristics for the new products put on sale and the selection of customers especially targeted for that sale. This simple and basic framework of two models works well with the empirical evidence available until 2020. On the one hand, the greening of electricity is strongly characterized by the kind of assets it requires to generate power, as well as the types of revenue streams that allow it to grow. On the other hand, the ongoing digitalization of retail-size units is deepening because of new products and new characteristics are

New Transactions in Electricity: Peer-to-Peer and Peer-to-X

Jean-Michel Glachant and Nilsch Reuter**

ABSTRACT

Peer-to-peer and peer-to-x opens a new world of transactions in the electricity sector. This world is characterized by the active involvement of new players, both small in size and non-professional in nature, and by new combinations of the activities carried out behind and in front of the meter. Peer-to-peer refers to transactions in which both the seller and the buyer are small in size and non-professional, whereas peer-to-x refers to transactions where only the seller is small and non-professional while the buyer is a different type of actor. Observations from the world of practice reveal the existence of multiple forms of peer-to-peer and peer-to-x transactions. The first part of the paper identifies six typical forms of transactions and illustrates them with concrete implementation cases. The second part simplifies such diversity of types and distinguishes only four families of transactions. The third shows the importance of three components which are essential to the functioning of this new world. They are the matching loop, as small players cannot sell or buy from other peers in reality; the pricing mechanism, as existing wholesale and retail markets exert pressure on incentives for activating peers; and the delivery loop, as peers must deliver via existing grids and system operators, except when trading directly within private networks.

Keywords: Peer-to-peer electricity, Transactive energy, Electricity markets, Digital platforms, Energy communities, Regulatory sandboxes

<https://doi.org/10.5471/2166-5896.10.2.216>

INTRODUCTION

Peer-to-peer (P2P) and peer-to-x (P2X) open up a new world of transactions in the electricity sector. We have already seen in the past business-to-business (B2B) with the wholesale markets, opening around 1990, and business-to-consumer (B2C) with the retail markets, opening around 2000 (Glachant et al. 2021). The new world of P2P and P2X electricity transactions has not yet been fully explored and characterized.¹ However, two key features of these new transactions are immediately notable. First, a particular set of players are involved. They are small in size and non-professional on both the supply and the demand side. This is why we call them ‘peers’. This represents a striking novelty because the electricity industry has traditionally been dominated by the opposite: big and fully professional players. Second, the

Flexibility at core of EU decarbonization strategy

- At the core of EU decarbonization strategy is **electrification** with **clean electricity**. This implies 6 times more Green electricity.
- 1- Decarbonizing the electricity EU consumes today 2,500 TWh
- +2 Direct electrification of road mobility 3,100 TWh , heating & cooling buildings & households 2,900 TWh, parts of industrial processes 1,000 TWh
- +3 Indirect electrification of maritime & aviation, other parts of industrial processes (via Green Hydrogen & Ammonia, etc.) 2,000 TWh. Competing with Biofuels? Synthetic fuels from gas + CCUS?
- Today's EU gas crisis reminds: “**Flexibility of electricity systems**” is key

Overview of electricity flexibility seen from consumer side

- First, **the supply of flexibility** on the consumer side, distinguishing 4 types of consumer flexibility (from demand response to system peaks, to integrating consumption in a transactive process)
- Then, **the uses of flexibility**, distinguishing 3 levels of flexibility use (⌘ at transmission level, ⌘ at distribution level, ⌘ and “*Behind-the-Meter*”)

Consumer Flex (1) Demand response to system peak pricing

- Not new, exists since decades that certain consumers gain by not consuming at peaks
- Tradition in France is ‘*EJP*’ = Demand response to seasonal peaks. Mainly professionals do that. But even households: in 2021, 22 ‘Red Days’ at 374 Euro a MWh (retail rate)
- New business for ‘*Aggregators*’ = Demand response at all peaks, incl. daily peaks. Made EU legal by *Clean Energy Package*, but rules (*Aggregators vs Suppliers*) left national. Leading French: *Voltalis*. Leading German: *Next Kraftwerke* (10,000 clients & 9GW in 2020). Business of ‘*Light Assets*’ intermediary & trader

Consumer Flex (1) Demand response to system peak pricing

- Expansion of electricity consumption via electrification of industrial processes will expand the potential business of demand response; and I have already seen industrials studying what could be the ‘right flexibility potential’ to give to their new investments.

Consumer Flex (2) Managing distributed generation with storage

- Expansion of rooftop PV questions the right size of PV assets vis-à-vis size of self-consumption; plus the lower storage costs expand set of choices for prosumers (1.2m in California)
- Management of distributed generation with storage opens the box of ‘price arbitrage’: grid tariffs for peak injection or withdrawal; supplier tariff for energy; support schemes for renewables... The prosumer can decide, act & react
- German company Sonnen sold > 60,000 home storages

Consumer Flex (3) Managing a flexible load being a storage: Electric Vehicles

- An EV is both a flexible load (it can charge at different points & different times) and a storage...
- ‘Smart Charging’ means making arbitrage for EV charging
- ‘Vehicle to Grid’ (V2G) adds options of injecting electricity into the grid > wider arbitrage perimeter.
- EV owners have to choose being active or passive; incl. for their car to be able to do V2G. But Volkswagen now installs V2G on all its EVs.
- EV owners can also arbitrage charging at home, work, or station
- 15% EU fleet to EV = 40 m cars => 2 TWh batteries ‘On Wheels’

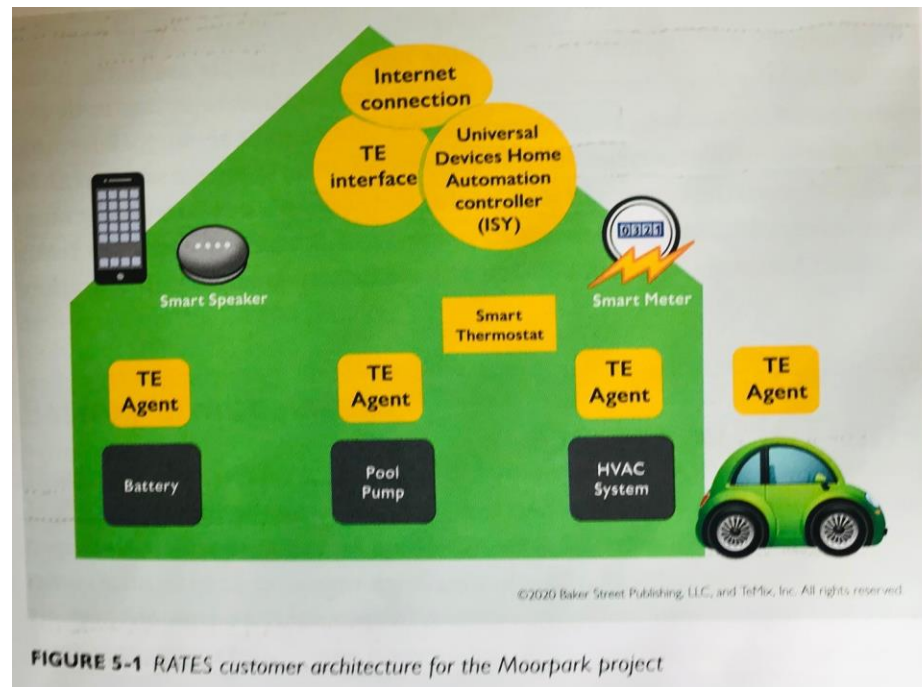

Consumer Flex (4) Integrating key consumption devices into a transactive process

- Not so easy for consumers to evaluate all options & manage well flexibility of home (or shop, or building) consumption
- But it can be automatized: via a proper digitalization of key consumption devices ('sensors' + 'actuators' + 'controller')
- Let's look at cases of '*transactive energy*' in the US

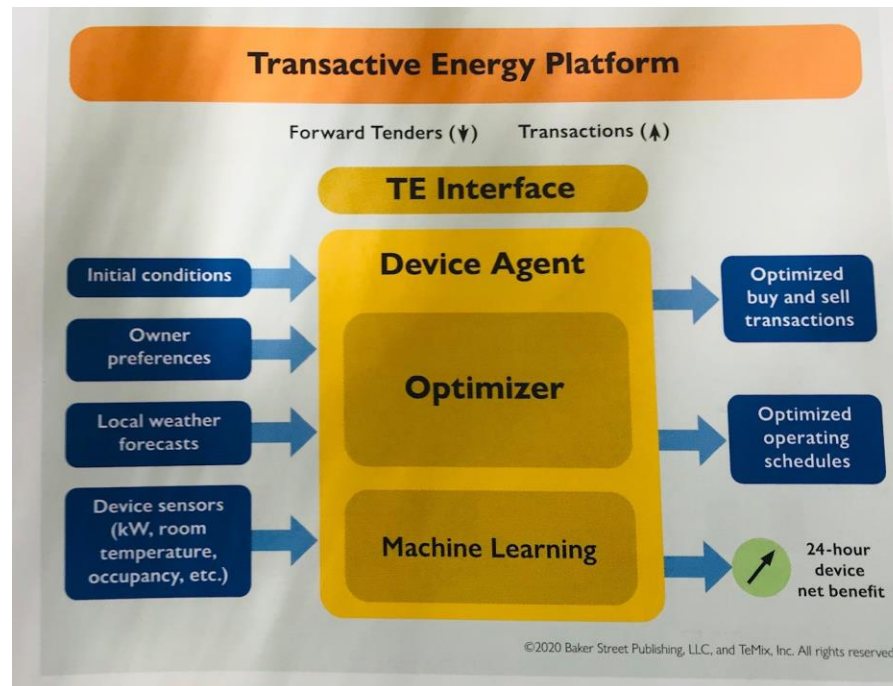

Proof of concept '*RATES*' in suburb of Los Angeles, for 3 years

Tested at scale in Colorado, '*TESS*', with 58,000 participants.

Each key device gets sensors + an actuator

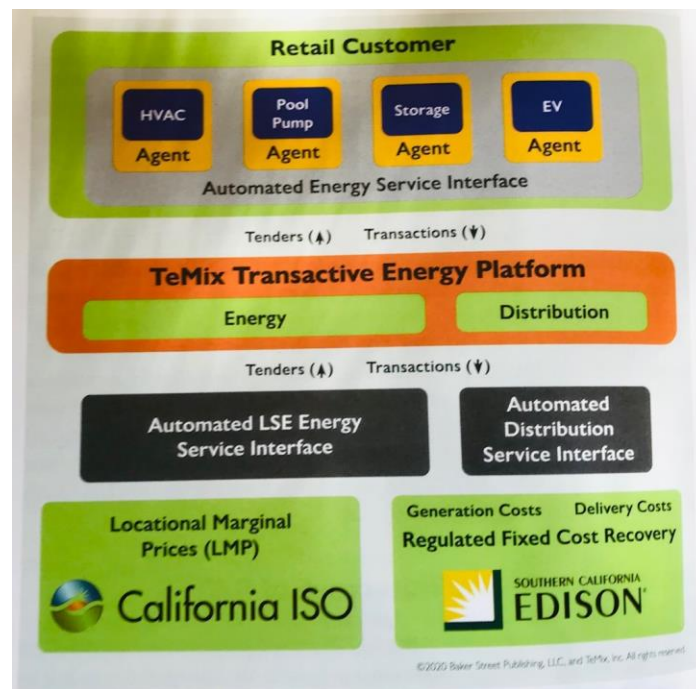

Each device obeys ‘owner preferences’ + ‘machine learning advices’ via a *Home Integrating Controller*

Txs to dedicated Platform

the *Home Controller* interacts with the System Operator pricing & the Supplier tariffs

Flex. Use Level (1) At Transmission level

- Needs of flexibility at transmission level vary from one country to another; in same country from one electricity mix to another
- French Transmission System Operator 'RTE' just released its '2050 Net Zero' study. Central scenario sees electricity consumption in 2050 at +200 TWh (+40%)
- IF 51 GW nuclear in 2050 (today 61 GW) & 135 GW renewables, Flexibility by demand response & V2G is at 15 GW ~ France SoS needs additional 1 GW system battery.
- IF 0 Nuclear & 345 GW renewables, France SoS needs additional 26 GW system battery & 29 GW decarbonized thermal plants.

Flex. Use Level (2) At Distribution level

- Another story... French TSO RTE expects 135GW to 345GW renewables in France 2050: 110 GW to 285 GW connected to distribution grids

Estimation of future distribution grid costs

EU27+UK annual investments in power distribution grids and key drivers
(nominal €bn; 2015-2030)

Flex. Use Level (2) At Distribution level

Flexibility as a tool to reduce network investments

The ratio of saving investment expansion

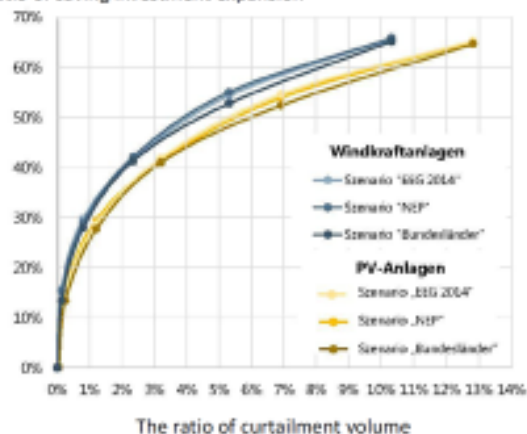

Figure 4: System welfare for different demand-side flexibility levels

Flex. Use Level (2) Distribution level Flex. Toolbox

CEER = EU regulators

- Network tariffs
- Connection agreements
- Market-based procurement
- Rules-based approach

E.DSO = EU DSOs

- Tariff solutions
- Connection agreement solutions
- Market-based solutions
- Rule-based solutions
- Technical solutions using grid assets

But there are 22 options: not agreed upon...

- Use case and voltage level
 - Congestion management and/or voltage control
 - Deferral of network investments
 - Planned maintenance
 - Incidents
- Market integration
 - TSO-DSO coordination
 - Timing and sequence in DAM/IDM
 - Single market vs series of call markets vs continuous market
- Market rules
 - Market objective
 - Integration of network constraints
 - Pricing scheme
 - Baseline approach
- Product definition
 - Tailored vs generic products
 - Fixed vs open attributes
 - Short vs long-term products
 - Active vs reactive power
- Roles and responsibilities
 - Market operator role
 - Market clearing role
 - Meter data operator role
 - (independent) aggregators
- Financial vs reputation vs regulatory incentives
- Calculation of cost and benefits flexibility markets
- Customer engagement

But EU Transm. & Distrib. Roadmap in June

Topics 100% agreement

α Measurement, Validation & Settlement 5

Topics 100% agreement

**α Product Design & Procurement 5 Topics 100%
disagreement**

**α Market Processes & Transmission –
Distribution coordination**

10 topics 40% disagreement

Flex. Use Level (3) *Behind-the-Meter*

- Aggregators & retailers play in the wholesale market. Retailers buy wholesale & fraction it for the consumers. Aggregators buy at consumers & repack at a wholesale size.
- Many other actions stay at the consumption level: *behind the meter* of the distribution grid. As: decentralized generation, decentralized storage, management of EV charging & V2G, etc.
- Here consumption flexibility can be directly integrated with operation of decentralized generation & decentralized storage. It is the 3d level of flexibility: the *Behind-the-Meter flexibility*.

Flex. Use Level (3) Behind-the-Meter

- Prosumers & Prosumagers can prefer to get the integration of their assets & consumption from an ‘asset light’ professional
- UK supplier Octopus does it for owners of a Tesla + Powerwall storage + RoofPV, guaranteeing the smallest price for all complementary energy supply
- Sonnen in Germany does something similar with the batteries it sells, offering an “Energy Community” to their owners. Highest Sonnen battery “*Econlix*” (10 kWh) also offered to control the consumption devices at home.
- Ausgrid & Reposit Power, in Australia, guarantee 5 years of free energy supply to all households investing into 6.6kW PV + 11.8kWh storage monitored & managed by Reposit Power ‘home controller’

Flex. Use Level (3) Behind-the-Meter

- The EU legal definition of ‘*Energy Communities*’ (in “Clean Energy Package”) might open the way to collective actions, independent of market-based suppliers’ undertaking.
- See coming pioneering community “Solar” in city of Allensbach (Baden-Wurtemberg) [*Innovation Award 2021* by RGI]
- Empowerment of prosumers & prosumagers can also give rise to “*Peer-to-Peer*” sharing of PV, storage, EV charging in a “*sharing economy*” scheme. *Digital Platforms* can play there a big role to simplify trade & transactions.

Conclusions

- 1st Wider electrification of EU energy systems will increase the role of decentralized resources, be they generation or storage, and the value of a deeper digitalisation of consumption devices, *Heat Pumps* or *EVs*. *Internet of Things* will permit billions of devices to emit, receive, act and interact.
- 2nd Proper regulatory frame to reach the full potential of this wave is not yet defined. But regulators, grid operators, utilities, independent businesses, prosumers, communities, EV owners are already thinking & testing. For the success of EU 2030 decarbonisation targets, one needs this EU Big Bang to succeed.

Many thanks to you all... If any wish list...
