| Labels ag | gainst Lemons | | |

- Products of uncertain quality could be unfairly valued by economic agents, due to information asymmetries (Akerlof, 1970). Today information failures on products' quality plague the development of eco-friendly consumption (Cason and Gangadharan, 2002)
 - Labels and certificates have acquired popularity among policy-makers, firms and NGOs.
- Energy Performance Certificates spread in the European Union as an answer to the energy-efficiency gap (Jaffe and Stavins, 1994): home appliances, vehicles and buildings.
- Mandatory in every French real estate transaction since a decade.

| Literatu | re | | |

- Hedonic approaches have demonstrated premiums for labelled energy-efficient houses,
 - In the United States, LEED and EnergyStar certifications induce a green premium for labelled buildings (Eicholtz et al., 2010).
 - In the European Union, hedonic analyzes of the EPC premiums over several countries: 3.7% in the Netherlands (Brounen and Kok, 2011), 9% in Ireland (Hyland et al., 2013), similar to England (Fuerst et al., 2015).
 - In France, Civel (2019) estimates the premium for highly efficient houses around 30k€.

 - In France, Civel (2019) estimates the premium for highly efficient houses around 30k€.
- 2 But is this premium really derived from the label?
 - Can't be sure with classical hedonic analysis,
 - Olaussen et al. (2017) on norvegian data tend to demonstrate that people might be able to estimate by themselves energy performance and not use EPC.

Our specificities

- Use of a very large data set of French real estate transactions, from 2014 to 2022, throughout the country,
- Estimation of the green premiums at EPC class frontiers through regression discontinuity design,
- 3 Analysis of certifiers behaviors.

| Data pre | eparation | | |

- EPC database with 3.5 millions observations,
- Real estate transaction database with 4.5 millions observations.
- Fused using geographic coordinates,
- Little challenging as GIS were not synchronized,
- Final clean database counts over 1.5 millions observations, which descriptive statistics closely match the ones of original databases, selection bias is probably low.

Regression Discontinuity Design - RDD

RDD, in its basic setup, relies on three elements: a **running variable**, a **cutoff** and a **treatment**.

- Two subsets of subjects are allocated to experimental and treatment groups as a function of an independent variable — the running variable.
- Subjects with running variables that exceed a certain threshold (or inversely, fall below it), will receive an experimental treatment.
- The boundary value of the running variable that determines the group status is referred to as cutoff.

18 / 23

- RDD results are robust to a donut-hole design, removing observations $5kWh/m^2$. year above and below cutoffs (the obviously manipulated zone).
- Market effects are thus explored.

- In our EPC database, we have a certifier ID code, which makes it possible to identify which EPCs have been realized by the same certifier.
- \Rightarrow We exploit the EPC dataset to understand what drives the probability of being just below a cutoff rather than just above.

Manipulation & Certifiers

22 / 23

Contributions

Main messages & further research

- Regression Discontinuity Design demonstrates that an insignificant change in houses energy consumption induces a significant one in the market price through a class change in the label, highlighting consumers' heuristic thinking.
- Certifiers manipulate heavily EPCs at class frontiers, probably in order to gain market shares by using convenient certificates as loss leaders.
